ABSTRACT: Observations of different extracts derived from plants of *Eclipta alba* Hassk, *Aloe barbadensis*, and *Piper longum* L revealed different pattern of leishmanicidal activities. Screening was done in late stationary phase promastigote culture of *L. donovani* (a causative protozoan parasite of Reticulo-endothelial system of human) by observing percent inhibition through microscopical counting after 24 hours of inoculation with different concentrations (0.25mg/ml and 0.5%mg/ml) plant origin. Propidium iodide (PI) was used to measure the effect of these plant extracts on the degree of damage to the parasite cell membrane by flow-cytometry. The present study showed that crude soluble preparation of *Eclipta alba*, —*Aloe vera* and *Piper longum*, recorded 96.7%,87.3% and 83.3% inhibition rate of Leishmanial promastigote in 0.5mg/ml concentration at 24th h of inoculation.

Key Words: Leishmanicidal herbs, Eclipta alba, Aloe vera, Piper longum, L. donovani.
